

“Astronomers Discover Complex Carbon Molecules in Interstellar Space”

A team led by researchers at MIT in the United States has discovered large molecules containing carbon in a distant interstellar cloud of gas and dust.

This is exciting for those of us who keep lists of known interstellar molecules in the hope that we might work out how life arose in the Universe.

But it's more than just another molecule for the collection. The result, reported today in the journal *Science*, shows that complex organic molecules (with carbon and hydrogen) likely existed in the cold, dark gas cloud that gave rise to our Solar System.

“After 29 years, first-known brown dwarf revealed as twins”

- **Brown dwarfs are ‘failed stars’** with masses greater than planets but less than stars. The first confirmed brown dwarf was Gliese 229 B in 1995.
- **But Gliese 229 B’s brightness is puzzling.** Based on its mass, it should be much brighter, said astronomers.
- **Now, astronomers say Gliese 229 B is two brown dwarfs,** not one, as they originally thought. The researchers said the two brown dwarfs orbit extremely close together.

“12 breathtaking images from the 2024 Astrophotography Prize Photographer of the Year awards”

Striking. Vibrant. Dazzling. The adjectives to describe our universe are nearly infinite. And nowhere is that on display more than in the images from this year's Astrophotography Prize Photographer of the Year awards.

Australian photographer Phil Hart took the top honors for his incredible image of the 2023 solar eclipse over Exmouth, Western Australia. Hart's photo is one of the highest-resolution (white light) images of the solar corona ever

documented, and its details are staggering. He created the image using multiple telescopes, video frames, and RAW exposures.

“A steam world exoplanet with an earthlike atmosphere?”

- **GJ 9827 d is an exoplanet orbiting a red dwarf star,** some 98 light-years away. It's about twice the size of

Earth and searing hot.

- **It's the smallest exoplanet so far where water vapor has been detected.** But does it have a hydrogen atmosphere, or a more earthlike atmosphere?
- **New results from the Webb space telescope** suggest an atmosphere dense with heavy molecules. This includes even more water vapor than first thought, suggesting the hot planet is a “steam world.”

“Fumes of Fiery Volcanic Moon Detected Outside The Solar System”

Around a neighboring star just 635 light-years away,

astronomers have found even more evidence of a moon absolutely livid with volcanoes.

There is a giant cloud of sodium consistent with volcanic activity, orbiting an exoplanet named WASP-49b, orbiting in turn a yellow dwarf star named WASP-49.

And how do we know that the sodium is from an exomoon? The exoplanet is a gas giant, unlikely to host volcanoes – and the sodium cloud is out of sync with the exoplanet's orbit, but exactly what we might expect if WASP-49b had a rocky volcanic moon.

“Earth’s core has a huge, hidden donut shape”

- **Earth's core is in two parts**, an inner solid core and a liquid outer core.
- **Scientists just discovered a large donut-shaped region** within the outer core. They used a new method of measuring seismic waves to find it.
- **Earth's magnetic field** is powered by the liquid outer core. The discovery provides new clues about the dynamics of the magnetic field.

“Another one! New comet could get SUPER-bright”

We've been eagerly waiting for bright Comet A3 to grace our skies. And now there's another comet! On Friday, the ATLAS survey discovered a comet that could appear even brighter than Comet A3, and even brighter than the brightest planet, Venus. Comets are notoriously unpredictable, but early observations suggest it might be bright enough to be seen *even in the daytime*.

The comet is so new it's still waiting for its name. But for now it has the designation of A11bP7I. Predictions for the comet have it reaching as bright as magnitude -5 to -7 when it comes closest to the sun, at perihelion, on October 28.

“Nikola Tesla & The Electric Universe | Thunderbolts”

It's not easy to categorize Tesla—engineer, inventor, futurist, humanist, and visionary—although his ideas about the universe resonate with the EU Model—electrical energy is a force in nature and a living, connected cosmos. David Drew examines the legacy of Tesla (1856–1943).

“What is the heliosphere and how can we measure it?”

The sun warms the Earth, making it habitable for people and

animals. But that's not all it does, and it affects a much larger area of space. The heliosphere, the area of space influenced by the sun, is over a hundred times larger than the distance from the sun to the Earth.

The sun is a star that constantly emits a steady stream of plasma – highly energized ionized gas – called the solar wind. In addition to the constant solar wind, the sun also occasionally releases eruptions of plasma called coronal mass ejections, or CMEs.

**“1.5 billion cosmic objects
dazzle in the largest
infrared Milky Way map ever
created”**

Astronomers from the European Southern Observatory (ESO) have released the most detailed infrared map of the Milky Way galaxy ever compiled. Completed after more than 13 years of monitoring using the ESO's Visible and Infrared Survey Telescope for Astronomy (VISTA) at the group's Paranal Observatory in Chile, the project adds up to 500 terabytes of data containing over 1.5 billion cosmic objects. Taken as a whole, the mapping is the largest survey of its kind to employ an ESO telescope.
